ENGG 151.01 - C

August 31, 2026

The C++ implementation of the normalized crosscorrelation program has been substantially completed. The program can import two signal files, determine their starting indices and durations, remove the signal averages, and compute the normalized crosscorrelation. The results were verified using the provided Basic Test and matched the expected values.

The program can also export the resulting crosscorrelation signal to an output file. Input validation and error handling were improved and tested using different cases, including comments, missing starting indices, decimal values, invalid input, blank lines, nonexistent files, and constant signals that cannot be normalized

As for the next progress report, the remaining work mainly focuses on final testing and checking the program and comparing it with Project 1 requirements. Additional required test signals and submission files will also be prepared before the final submission.
